Abstract

Background: Inflammatory sinonasal diseases (ISD) refer to a group of disorders characterized by inflammation of the mucosa of the PNS. Acute ISD are defined as sudden in onset and duration less than 3 weeks. Recurrent acute infections are defined as four or more attacks per year lasting greater than 7-10 days. Chronic is defined as duration of symptoms more than 12 weeks.

Materials and methods: The present prospective study was conducted in the department of ENT JSS Medical College and Hospital. The study was conducted from a period of November 2012 to June 2014. The study included a total of 50 patients with clinically proven inflammatory sinonasal diseases not responding to medical line of treatment. A complete detail about their signs and symptoms was also recorded in a tabulated form. Data was expressed as percentage of the total information and analysis was done using SPSS software.

Results: The present study enrolled 50 subjects, out of these; there were 21 females and 29 males. 56% were diagnosed as with chronic sinusitis, 30% with ethmoid polyposis and 14% with antrochonal polyp in this study. The specificity of CT was found to be best for posterior ethmoid, hiatus semilunaris, sphenoethmoid recess, uncinate process, frontal recess, inferior turbinate. The values were 97%, 89%, 95%, 93.5%, 89.5% and 88.5% respectively. CT was relatively less sensitive for anterior ethmoid, infundibulum, bulla ethmoidalisad maxillary sinus. The values were 86%, 85%, 71%, 66%.
Conclusion: CT is effective in demonstrating predisposing cause of Inflammatory Sino nasal diseases (e.g. Anatomical variants) and provides guidance for therapeutic endoscopic instrumentation. CT with its excellent capability for displaying bone and soft tissue is the current diagnostic modality of choice for evaluation of osteomeatal complex. CT scan has to be done, to know sino nasal anatomy and anatomical variations and to plan for FESS. CT scan provides findings which helps in management and acts as Road Map to the surgeons if FESS is indicated.

Key words
CT scan, Intra operative, Inflammatory sinonasa disease.

Introduction
Sinusitis is defined as inflammation of one or more paranasal sinuses. Based on the causative organism it can be bacterial or viral. Viral sinusitis takes around 7-10 days to resolve whereas bacterial sinusitis is generally persistent [1]. The various bacterial pathogens responsible for causing bacterial sinusitis include hemophilus influenza, streptococcus pneumonia and moraxella catarrhalis [2]. In cases of chronic sinusitis there is variation of anaerobic species from 80% to 100% in case of children [3], to only 0 to 25% in case of adults [4, 5]. Chronic headache is one of the most common symptoms which are distressing to both patients and physicians.

Due to the nagging nature of patients and inability of the physician to diagnose and problems of self-medications, nature of headache remains undiagnosed in spite of many elaborated battery of tests. The major symptoms include facial pressure or pain, nasal obstruction, discharge or purulence, and hyposmia or anosmia. The minor symptoms include fever, halitosis, fatigue, and dental pain. Microorganisms play a significant role in the persistence and origination of the inflammatory process, although the exact role of these organisms in the pathogenesis of inflammatory sino nasal diseases is unclear. The diagnosis relies on clinical judgment based on a number of subjective symptoms and few findings in physical examination. Surgical clearance of these chronically infected sinuses while maintaining their ventilation and drainage is the treatment of choice. To achieve this goal there should be some diagnostic modality which guide as towards exact diagnosis and safe intervention. Over the past decade, both CT and nasal endoscopy have been used successfully as diagnostic modality in sinus disease. The aim of the present study is to determine the most commonly associated clinical features of sinusitis.

Materials and methods
The present prospective study was conducted in the department of ENT, JSS Medical College and Hospital. The study was conducted from a period of November 2012 to June 2014. The study included a total of 50 patients with clinically proven inflammatory sinonasal diseases not responding to medical line of treatment. Both males and females aged between 18-60 years were included in the study. Patients with acute attack of ISD, malignancies, any previous paranasal surgery or granulomatous disease of nose and paranasal sinus were excluded from the study. All the subjects were informed about the study and a written consent was obtained from all. The study was approved by the institutional ethical board. A detailed history and demographic details of all the subjects was obtained and a complete blood analysis of all the patients was performed. It included estimation of hemoglobin method, total and differential leukocyte count, platelet count and bleeding and clotting time. All the patients were prescribed a suitable course of antibiotics, nasal decongestants and anti histaminics. A complete detail about their signs and symptoms was also recorded in a tabulated form. Data was expressed
as a percentage of the total information and analysis was done using SPSS software.

**Results**

The present study enrolled 50 subjects, out of these; there were 21 females and 29 males. Middle meatal antrostomy, infundibulectomy along with anterior ethmoidectomy was done in all the cases while septoplasty, posterior ethmoidectomy and sphenoidectomy were done in some cases. 56% were diagnosed as with chronic sinusitis, 30% with ethmoid polyposis and 14% with antrochonal polyp in this study. Diagnosis of patients was chronic sinusitis in 28 (56%) cases, Sinus nasal polyposis ethmoidal polyp in 15 (30%) cases and Antrochonal polyp in 7 (14%) cases out of 50 (100%) cases. The various parameters were correlated in our study were inferior meatus, inferior turbinate, middle meatus, middle turbinate, infundibulum, uncinate process, maxillary sinus, hiatus semilunaris, bulla ethmoidalis, anterior ethmoids, posterior ethmoids, sphenoid recess and frontal recess. The sensitivity and specificity of CT as compared to OT were calculated for each parameter. CT showed highest sensitivity for anterior ethmoid, posterior ethmoids, uncinate process, sphenoid recess, inferior turbinate was 92%, 95%, 94.5%, 96% and 94% respectively. CT was found less sensitive for parameter like infundibulum, maxillary sinus, and middle meatus. The values were 76.5%, 73%, 88% respectively. The specificity of CT was found to be best for posterior ethmoid, hiatus semilunaris, sphenoid recess, uncinate process, frontal recess, inferior turbinate. The values were 97%, 89%, 95%, 93.5%, 89.5% and 88.5% respectively. CT was relatively less sensitive for anterior ethmoid, infundibulum, bulla ethmoidalisad maxillary sinus. The values were 86%, 85%, 71%, 66%.

**Discussion**

CT is effective in demonstrating predisposing cause of Inflammatory Sino nasal diseases (e.g. Anatomical variants) and provides guidance for therapeutic endoscopic instrumentation. CT with its excellent capability for displaying bone and soft tissue is the current diagnostic modality of choice for evaluation of osteomeatal complex.

**Conclusion**

In the overall assessment, following conclusions can be drawn: Chronic sinusitis was the common malady. Majority of the patients were in the third decade with male predominance. Commonest symptoms were nasal obstruction and headache along with nasal discharge. Middle meatus discharge, an edematous mucosa and polyps were the commonest signs encountered. Maxillary sinus was most frequently diseased sinus in our study. Anatomical variants were very well recognized on CT scan. Nasal endoscopy can prove to be a better diagnostic modality compared to CT scan when conditions like middle meatal secretions, condition of mucosa, polyps were looked for. The evaluation ISD should be done after maximum medical therapy. Conventional Skiagrams have no role in evaluation. The study stresses that in all patients with Inflammatory sino nasal diseases, CT scan has to be done, to know sino nasal anatomy and anatomical variations and to plan for FESS. CT scan provides findings which helps in management and acts as Road Map to the surgeons if FESS is indicated.
